It will be sufficiently accurate to let  $ir^2 = 10$ . b. What sources of error in your experiment have you not allowed for? Example: Suppose that a pendulum 64TM1 long makes 37 double vibra 372 tions in a minute; then  $g = 4 Ttwi = 4 \times 10 \times 64 = 974 \text{ cm} = 9.74 \text{ m}$ . HEAT. 01. Ap.: board on which are fastened wires of (1) iron, (2) copper, (3) brass, and (4) German silver (Fig. 33); and alcohol or Bunsen burner. a. If you find the wires hot, cool them by thrusting the heated ends into water. Support the board in a horizontal position, and place a lamp flame where the wires meet, so that all the wires will have an equal opportunity to get heated. Place a finger on both the iron and copper wires, near the flame, retreating as the heat becomes unbearable. You will, in time, find that the points which you touch reach a stationary stage; i.e. these points lose heat as fast as they receive it. Find the relative distances of the bearable points of the several wires from their heated ends, and arrange the metals in the order of their conductivity, beginning with the best conductor. The exact relative conductivity of these metals cannot be ascertained by comparing these lengths, as other things beside conductivity enter somewhat into the computation. b. In what way do points along the wires lose heat, so that they ultimately reach...
